

HTTP by Hand & Project Setup

Goal

Show you can form an HTTP request by hand and read the response, and set up the **CampusEats** project.

Approach

Work the way **Tutorial 1** showed: send HTTP by hand with **curl**, and inspect a real page with the browser's **DevTools → Network** panel. Document exactly what you run and what comes back.

Tasks

1. Using **curl -i**, make at least five requests to a public, read-only JSON API. Capture the full request and response each time. At least one request must deliberately fail — ask for something that does not exist and capture the 404. Add a one-line note on what each status code and Content-Type means.

Submit — *http-log.md* — five annotated request/response pairs, one of them a 404.

2. Open any website, open **DevTools → Network**, tick “Disable cache”, and reload. Read the waterfall of requests.

Submit — *network-analysis.md* — the request count, total page size, the single slowest resource, and any 3xx/4xx you see.

3. Create a Git repository named **campuseats**, with a clear structure (a README, a docs/ folder). Commit as you work — not final commit.

Submit — the repository link — with a real README and a readable commit history.

4. Write a one-page **CampusEats brief** in your own words: what the system does, who uses it, its **nouns** (the things/ services) and its **verbs** (the actions/ tasks/contracts).

Submit — *brief.md* — what / who / nouns / verbs, with the nouns and verbs listed explicitly.

What to submit

The link to your **campuseats** GiT repository, containing these four files:

- README.md, http-log.md, network-analysis.md, brief.md
